(54) Title: MYCOBACTERIAL SPECIES-SPECIFIC REPORTER MYCOBACTERIOPHAGES

(57) Abstract

This invention relates to mycobacterial species-specific reporter mycobacteriophages (reporter mycobacteriophages), methods of producing such reporter mycobacteriophages and the use of such reporter mycobacteriophages for the rapid diagnosis of mycobacterial infection and the assessment of drug susceptibilities of mycobacterial strains in clinical samples. In particular, this invention is directed to the production and use of luciferase reporter mycobacteriophages to diagnose tuberculosis. The mycobacterial species-specific reporter mycobacteriophages comprise mycobacterial species-specific mycobacteriophages which contain reporter genes and transcriptional promoters therein. When the reporter mycobacteriophages are incubated with clinical samples which may contain the mycobacteria of interest, the gene product of the reporter genes will be expressed if the sample contains the mycobacteria of interest, thereby diagnosing mycobacterial infection.

MYCOBACTERIAL SPECIES-SPECIFIC REPORTER MYCOBACTERIOPHAGES

STATEMENT OF GOVERNMENT INTEREST

This invention was made with government support under NIH Grant Number AI26170.

FIELD OF THE INVENTION

This invention relates to mycobacterial species-specific reporter mycobacteriophages (reporter mycobacteriophages), methods of making the use of reportermycobacteriophages, and reporter mycobacteriophages, for example, to rapidly diagnose mycobacterial infection and to assess drug · susceptibilities of mycobacterial strains in clinical 10 Specifically, this invention relates to the samples. mycobacterial species-specific luciferase use o£ reporter mycobacteriophages to diagnose tuberculosis and to assess the drug susceptibilities of the various Mycobacterium tuberculosis 15 of strains (M. tuberculosis).

To produce the mycobacterial species-specific reporter mycobacteriophages of the invention, transcriptional promoters and reporter genes are introduced into the genomes of mycobacterial

species-specific mycobacteriophages. These reporter genes may be the genes for luciferase or the ß-galactosidase gene, and provide the DNA which encodes production of a gene product. The reporter

- mycobacteriophages may be used by incubating same with samples which may contain the specific mycobacteria of interest. If the mycobacteria of interest is present, then the reporter mycobacteriophages introduce the recombinant nucleic acids which encode expression of
- the gene product into the mycobacteria of interest, and the mycobacteria then express the gene product.

 The expressed reporter gene product may be detected by a suitable assay, for example, through the detection of photons or the conversion of an easily assayable
- chemical reaction. The presence of such gene product indicates that the sample contains the mycobacteria of interest, and hence the mycobacterial species-specific reporter mycobacteriophages may be used to detect and thereby diagnose the specific mycobacterial
- infection. In addition, since signals may not be generated by cells which are not metabolically active in the presence of antibiotics, the mycobacteria species-specific reporter mycobacteriophages of this invention may be used to assess the drug
- 25 susceptibilities of various strains of mycobacteria.

 If antibiotic drugs are added to the sample containing the reporter mycobacteriophages and the gene product

20

is detected, the mycobacteria is metabolically active and hence resistant to the antibiotic drug.

BACKGROUND OF THE INVENTION

In 1990, there was a 10% increase in the incidence of tuberculosis in the United States. addition, there has been an increase in the appearance of clinical isolates of tuberculosis that resistant to antibiotics used to treat the disease. This problem is exacerbated by the length of time that is currently needed both to diagnose tuberculosis, 10 and to determine the drug susceptibilities of various strains of M. tuberculosis. As a result, patients with M. tuberculosis may remain infectious for long periods of time without being treated, or may be treated with a drug to which the bacterial strain is resistant. Therefore, a need has arisen in the field for a method of diagnosis of M. tuberculosis (and other mycobacterial infections) which is rapid, sensitive and specific, which method is also capable of assessing the drug susceptibilities of the various strains of M. tuberculosis and other mycobacterial strains. It is critical that a mycobacterial strain be assessed for drug resistance rapidly because a patient infected with a strain of M. tuberculosis or another mycobacteria must be treated immediately with the particular antibiotic drug(s) to which the strain is not resistant, and not with antibiotic drug(s) to

15

20

25

which the strain is resistant, or the patient may die.

Currently, the most rapid test available for the diagnosis of M. tuberculosis is the staining of sputum samples for acid-fast bacilli, which is a tedious procedure, and which procedure has methods for diagnosis Alternative sensitivity. require cultivation of the bacilli for approximately two to six weeks followed by classification of the cultured organism. Typical diagnostic tools include biochemical tests, analysis of mycolic acids and serotyping. All of these tests are time-consuming. More recently, the use of oligonucleotide probes and Polymerase Chain Reaction have been suggested for the identification of M. tuberculosis species. Although these methods may be useful approaches, their uses in a clinical setting have not yet been determined. Further, these methods do not distinguish between live and dead organisms, and are therefore of limited use in the determination of drug sensitivities of clinical isolates.

In addition, Mycobacterium avium (M. avium) is a mycobacteria which is often found in immunosuppressed patients. This mycobacteria is typically disseminated throughout the bodies of immunosuppressed patients, such as AIDS patients, and causes M. avium infection. Because this mycobacteria often causes death in immunosuppressed patients, it is

25

necessary to be able to diagnose and assess the drug susceptibilities of the various strains of \underline{M} . avium.

It is therefore an object of this invention to construct broad mycobacterial host range and

5 mycobacterial species-specific reporter mycobacteriophages.

It is another object of this invention to provide mycobacterial species-specific reporter mycobacteriophages which may be used to rapidly diagnose mycobacterial infections.

It is still another object of this invention to provide mycobacterial species-specific reporter mycobacteriophages which may be used to rapidly assess the drug susceptibilities of different strains of mycobacteria in clinical samples.

It is yet another object of this invention to provide mycobacterial species-specific reporter mycobacteriophages wherein the reporter genes are luciferase genes, which mycobacterial species-specific reporter mycobacteriophages may be used to rapidly diagnose mycobacterial infections and to rapidly assess the drug susceptibilities of various strains of mycobacteria.

It is a further object of this invention to provide mycobacterial species-specific luciferase gene reporter mycobacteriophages which may be used to rapidly diagnose tuberculosis and assess the drug

susceptibilities of the various strains οf M. tuberculosis. ing the same of the con-

SUMMARY OF THE INVENTION

This invention relates to broad host range and 5 mycobacterial species-specific reporter mycobacteriophages, (reporter mycobacteriophages), methods of producing such reporter mycobacteriophages, and the use of such reporter mycobacteriophages to rapidly diagnose mycobacterial infection, such as 10 M. tuberculosis, and to distinguish which strains of the mycobacteria are drug-resistant. To produce these reporter mycobacteriophages / reporter genes transcriptional promoters are introduced genomes of mycobacterial species-specific

- mycobacteriophages. The promoter and reporter gene-containing mycobacteriophages (reporter mycobacteriophages) are then incubated clinical sample which may contain the mycobacteria of interest, such as M. tuberculosis. The reporter mycobacteriophages are specific for the mycobacteria which is sought to be detected. reporter mycobacteriophages efficiently introduce the recombinant nucleic acids which encode the expression of the reporter gene's gene product into the mycobacteria of interest, and the mycobacteria then
- 25 express the gene product. A substrate or other means

capable of allowing for the detection of the gene product is then added to the sample. If the gene product or the signal generated by the gene product is detected, the presence of the infectious mycobacteria

- is known, thereby diagnosing the disease. To assess drug susceptibility of mycobacteria, drugs such as antibiotics ma, be added to a sample containing the reporter mycobacteriophages of this invention. If the mycobacteria are susceptible to a drug after exposure to the drug, the mycobacteria will be killed.
 - However, drug-resistant mycobacteria will continue to be metabolically active in the presence of the drug, and will continue to express the detectable gene product of the reporter genes.
 - invention are the Firefly luciferase <u>lux</u> gene (FF<u>lux</u>),
 the luciferase <u>lux</u> genes of <u>Vibrio fischeri</u>, the
 luciferase <u>lux</u> genes of <u>Xenorhabdus luminescens</u> and
 the <u>E. coli</u> B-galactosidase gene (<u>lac</u>Z). The
 - preferred promoters of the present invention are hsp60 and L5 gene 62 promoter, and the preferred mycobacteriophages are L5, TM4 and D56A. These reporter mycobacteriophages are preferably used for the rapid diagnosis of tuberculosis and M. avium
 - 25 infection, and the accurate assessment of drug susceptibilities of the various strains of M. tuberculosis and M. avium.

BRIEF DESCRIPTION OF THE DRAWINGS

The above brief description, as well as further objects and features of the present invention, will be more fully understood by reference to the

following detailed description of the presently preferred, albeit illustrative, embodiment of the present invention when taken in conjunction with the accompanying drawings wherein:

FIGURE 1 represents the genome organization of mycobacteriophage L5;

FIGURE 2 represents a luciferase shuttle plasmid pYUB180 wherein reporter gene FFlux is fused to the BCG hsp60 promoter;

FIGURE 3 represents the amount of luciferase activity of M. smeamatis which contains the pYUB180 shuttle plasmid and the FFlux gene;

FIGURE 4 represents the effect of various antibiotic drugs on the metabolic activity of control mycobacteria and drug resistant mycobacteria in the

20 presence of reporter mycobacteriophages which contain luciferase reporter genes;

FIGURE 5 represents shuttle plasmid phAE39 wherein the reported gene is FFlux, the promoter is hsp60, the phage is TM4 and the cosmid is pYUB216.

FIGURE 6 represents luciferase activity of

M. smegmatis cells infected with shuttle phasmids
phAE39; and

15

20

25

FIGURE 7 represents a flow chart for cloning different promoters into TM4:: lux shuttle phasmid phAE39.

DETAILED DESCRIPTION OF THE INVENTION

This invention is directed to mycobacterial species-specific reporter mycobacteriophages, (reporter mycobacteriophages), methods of producing such reporter mycobacteriophages and the use of such reporter mycobacteriophages for the rapid diagnosis of mycobacterial infections and the accurate assessment of mycobacterial drug susceptibilities.

order to produce such mycobacteriophages, mycobacterial species-specific mycobacteriophage genomes are modified by introducing therein transcriptional promoters and reporter genes whose gene product can be sensitively detected. reporter mycobacteriophages may then be incubated with clinical samples suspected of containing the mycobacteria of interest, either directly of after culture, and the samples tested for the presence of the reporter product, thereby diagnosing gene mycobacterial infection.

The method of this invention allows for rapid diagnosis because only the amount of time necessary for the reporter mycobacteriophages to infect their host cells and the amount of time necessary for the host cells to synthesize the reporter gene product are

required to allow for diagnosis. Typically, the amount of time required for the reporter mycobacteriophages to infect their host cells and for the host cells to synthesize the reporter gene product is between ten minutes and sixteen hours.

The assessment of drug susceptibilities with the reporter mycobacteriophages of this invention is accurate because the reporter mycobacteriophages only allow for the detection of metabolically active mycobacterial organisms, the presence of which metabolic activity indicates that a drug has not killed the mycobacteria and that the mycobacteria is resistant to the drug.

To enhance diagnosis specificity, a series of similar reporter mycobacteriophages, each of which having well-defined but different specificities for mycobacterial species, is selected.

Mycobacteriophage L5, a temperate virus with a broad host-range among mycobacteria, is the most thoroughly characterized of the mycobacteriophages. L5 particles are morphologically similar to the family of phages that includes phage g and contain a linear dsDNA genome with cohesive ends. The inventors have determined the DNA sequence of the entire gene as well as several gene functions. The DNA sequence of the L5 mycobacteriophage is as follows:

It is known that during the establishment of lysogeny, the L5 genome becomes integrated into the mycobacterial chromosome and the attachment site (attP). Integration-proficient plasmid vectors have been constructed which efficiently transform both fast-growing and slow-growing mycobacteria through stable integration of the plasmid sequences into the bacterial chromosomal attachment site (attB).

Because the L5 sequence is now known, and because L5 has been previously characterized, the use of transcriptional promoters with this mycobacteriophage may be evaluated efficiently, and host synthesis inhibition may also be evaluated efficiently.

Figure 1 represents the genome organization of the entire L5 genome. DNA analysis has indicated that the L5 genome is organized into a right and left arm with the attachment site and integrase at the center of the genome. The integration functions have been successfully employed to construct integration-proficient vectors for mycobacteria.

Part of the L5 genome is not essential for mycobacteriophage growth. It has been demonstrated that all or most of the gene 62-61-60 can be deleted without affecting the cycle of the L5 phage. Therefore, there is a suitable region in the L5 mycobacteriophage for the insertion of reporter

15

20

genes. It is critical that reporter genes be inserted into non-essential regions of the mycobacteirophage. Otherwise, the mycobacteriophage will be unable to survive and replicate.

The L5 mycobacteriophage may have introduced therein promoter gene 62 fused to reporter gene lacz, and this reporter mycobacteriophage will be capable of diagnosis of mycobacterial infection rapid accurate assessment of mycobacterial strain drug susceptibilities: Armay read and the map of a

Another mycobacteriophage which may successfully used to produce the reporter mycobaceriophages is the mycobacteriophage TM4. TM4 has been used to construct a first generation reporter mycobaceriophage, and has the ability to discriminate between M. tuberculosis and BCG. A shuttle plasmid may be employed with TM4, and may be useful in the construction of recombinant and mycobacteriophages. Unlike L5, which is a broad host-range mycobacteriophage, TM4 species-specific mycobacteriophage. However, TM4 not as well characterized as the L5 mycobacteriophage, and therefore it is more difficult to analyze its functions.

- 25 DS6A is a mycobaceriophage that has been found to be specific for the M. tuberculosis complex of mycobacteria. It has been shown to infect both

10

15

20

25

M. tuberculosis and BCG. It has been demonstrated that DS6A can infect over 3,000 different types of M. tuberculosis strains. Current efforts are under way to develop DS6A shuttle phasmids containing Firefly luciferase genes as the reporter molecule. Ιt is possible that a combination of different needed be mycobacteriophages may ability the increase and then specificity distinguish drug susceptibilities. DS6A grows on BCG and M. tuberculosis, but does not grow on M. smegmatis.

In anticipation of the need for a diverse set of mycobacteriophages that can effect limited range of mycobacterial cells, a total of more than 50 unique mycobacteriophages have been collected new and isolated the inventors. by mycobacteriophages have been isolated from soil samples from India, France, England, Israel, Tunisia, In addition, another 30 Carville, LA and New York. mycobacteriophages from both the Centers for Disease Control in Atlanta and the World Health Organization Amsterdam Reference Laboratory in Phage collected. The characterization of the nucleic acid content of the phage particles of 30 ο£ mycobacteriophages have revealed that all of the mycobacteriophages contain double stranded DNA whose genome sizes range from 45 to 100kb as sized on pulsed field gels. Restriction analysis has shown that all

of these mycobacteriophages are different; except that one of the mycobacteriophages from France had a considerable similarity to the L5 mycobacteriophage, which was originally isolated in Japan. The host range of the mycobacteriophages varies greatly, some being able to infect only M. smegmatis and others smegmatis, BCG M. infect able to being M. avium. These not M. tuberculosis, but mycobacteriophages may be developed into reporter mycobacteriophages and cosmid cloning systems, and may provide a source of useful transcriptional translation initiating sequences, transcriptional terminators, or host-range specificity genes.

In addition, the choice of reporter gene and

its method of expression are critical. It is

necessary to choose a reporter gene whose product

would not normally be found in clinical samples, but

whose product is also easily detectable.

Luciferase reporter genes have been used in

20 many diversified biological systems, including

E. coli, cyanobacteria, phytopathogenic bacteria and

Bacillus. The presence of luciferase reporter genes

can be detected by the emission of photons in the

presence of a substrate, such as luciferin or

25 decanal. Luciferin and decanal can permeate

mycobacteria, and thereby allow for the detection of

gene products, such as photons. Since one molecule of

the luciferase gene product can yield 0.85 photons of light, it is the most sensitive biological reporter molecule known. The preferred reporter genes of this invention are luciferase reporter genes, such as the Firefly <u>lux</u> gene (FF<u>lux</u>), the <u>Vibrio fischeri lux</u> genes and the <u>Xenorhabdus luminescens</u> <u>lux</u> genes, as well as the <u>E. coli</u> ß-galactosidase (<u>lac</u>Z) Luciferase genes, especially the Firetly lux gene, geneate a high amount of luminescence activity. generate photons, the detection of which is simple and sensitive, using commercially available luminometers that can detect 100-1000 molecules of luciferase with a linear relationship to enzyme concentration. addition, it is unlikely that clinical samples will contain significant levels of endogenous luciferase activity.

In choosing transcriptional promoters to introduced into mycobacteriophages, it the desirable to use strong promoters since this will increase the sensitivity of the system. In addition, 20 it is important that the promoter be active following mycobacteriophage infection. The best promoter. candidates currently available are the BCG promoter and the L5 gene 62 promoter, which are of comparable strength. The hsp60 promoter gives good 25 levels of luciferase expression plasmid recombinants, but lower levels of luciferase

10

15

25

expression where the mycobacteriophage is TM4. It is possible that the reason for this is that the hsp60 promoter is shut off by the TM4 enzymes following infection, thus producing only a modest level of luciferase. The gene 62 promoter may behave in a similar manner with the TM4 phage since the gene 62 product is a good candidate for the L5 repressor and is expressed at high levels in the absence of other mycobacteriophage functions. Knowing the sequence of the mycobacteriophage used will help in identifying, characterizing and cloning the appropriate promoter to be used in the reporter mycobacteriophages of this invention.

There are several methods which can be introduce the reporter genes utilized to into mycobacterial transcriptional promoters species-specific mycobacteriophages. One method the utilization of shuttle phasmids. When utilizing shuttle phasmid technology, it is necessary to know the sequence of the mycobacteriophage so that the reporter genes are inserted into non-essential regions of the mycobacteriophage. Insertion of reporter genes into non-essential regions permits mycobacteriophage to survive and replicate. In order to use the shuttle phasmid methodology, necessary to first generate a cosmid library of large fragments double-stranded recombinant DNA

mycobacteriophage. This can be done using cosmid cloning in <u>E. coli</u>. Next, the cosmid library is introduced into the mycobacteria of interest to select for cosmids which have been inserted into

5 non-essential regions of the mycobacteriophage. The shuttle phasmids, which consist of the <u>E. coli</u> cosmid, the reporter genes and mycobacteriophage promoters, may then be characterized. Shuttle phasmids can be propagated in <u>E. coli</u> as plasmids, and propagated in mycobacteria as mycobacteriophages.

A second method of introducing the reporter genes and transcriptional promoters into mycobacteriophages is by homologous recombination or PCR. First, non-essential regions of a

- mycobacteriophage must be determined. Again, in order to do this, it is necessary to know the sequence of the mycobacteriophage. Consequently, L5 is an ideal phage to use with this method as its genome has already been sequenced and characterized by the inventors. Next, plasmids are constructed wherein
- inventors. Next, plasmids are constructed wherein reporter genes hooked to transcriptional promoters are flanked by mycobacteriophage non-essential region sequences in mycobacterial plasmids. Then, homologous recombination systems or PCR may be utilized in
- M. smegmatis or E. coli to perform gene replacement whereby the plasmid constructs containing the reporter genes are put into mycobacteriophages.

10

15

20

25

A third method of introducing reporter genes and transcriptional promoters into mycobacteriophages is by use of transposons. For example, transposon IS1096 may be utilized. In order to use this

methodology, reporter genes and transcriptional promoters are put into transposons, and the transposons containing the reporter genes and transcriptional promoters are delivered on plasmids in mycobacteria. Next, it is necessary to grow up the mycobacteriophages on a strain such as M. smegmatis, which strain contains the transposons. At certain frequencies, the transposons will hop into non-essential regions of the mycobacteriophages, thereby introducing themselves therein. The mycobacteriophages are still viable, and contain the reporter genes and transcriptional promoters.

A fourth method of introducing reporter genes and transcriptional promoters into mycobacteriophages is by debilitated phages packaged into phage heads and tails (phage particles). To utilize this methodology, it is necessary to develop helper phage systems which allow for pieces of DNA containing pac sites to be packaged. These helper phages allow for the synthesis of head and tail genes at will in mycobacteria, prevent themselves from being packaged into phage heads and tails, and facilitate packaging of pacmids into phage heads and tails. Helper phage systems may

15

20

25

generated from the L5 mycobacteriophage. be put into the of the helper phage is mycobacterial chromosome, at which the mycobacteria are grown up. Next, pacmids which comprise phages which have pac sites, reporter genes, transcriptional promoters and mycobacterial replicons are transformed onto the mycobacterial strain. production of head and tail proteins may be induced, for example, through an increase in temperature, and the pacmids are then packaged into phage heads and The L5 genome has cohesive (cos) termini. tails. This suggests the possibility of constructing cosmid vectors, which could be packaged through the cos sites into L5 particles either in vivo or in Then, a large number of genes could be easily and efficiently delivered to mycobacteria.

Packaging into phage heads and tails may also be utilized in a fifth methodology wherein the pacmid is a plasmid. The methodology is similar to the methodology wherein a debilitated phage is used, however, instead of using phage pacmids, the pacmids comprise plasmids which have pac sites, reporter genes, transcriptional promoters, and plasmid replicons.

Finally, direct cloning using recombinant DNA techniques in vitro may be used to introduce reporter genes and transcriptional promoters into

15

(52

mycobacteriophages. This methodology consists of ligating a mycobacteriophage, identifying or introducing unique restriction enzyme sites in non-essential regions of the mycobacteriophage,

- cleaving the mycobacteriophage with the restriction enzyme sites, and cleaving DNA which encodes the promoter and the reporter gene so that it has the unique sites flanking it on either side. Next, ligation is set up in vitro between the cleaved
 - mycobacteriophage with the unique restriction enzyme sites and the reporter gene cassette. The result is a circular DNA molecule which consists of the mycobacteriophage, the reporter genes and the transcriptional promoters. The circular DNA may then be electroporated directly into mycobacteria.

EXAMPLES

Expression of Reporter Gene lacZ and FFlux in Mycobacteria

incorporated a truncated E. coli ß-galactosidase

(lacZ) gene as a reporter probe into a shuttle plasmid vector that replicated in either mycobacteria or

E. coli. Random DNA fragments from the three mycobacteriophages Ll, TM4 and Bxbl were cloned into a unique BamHl site immediately upstream of the lacZ gene and screened for their ability to produce ß-galactosidase. This established that lacZ could be

used as a reporter gene in the mycobacteria, and identified the DNA sequences which could effectively express foreign genes in both M. smegmatis and M. tuberculosis. B-galactosidase activity could be detected from lysed cells using OMPG, or from unlysed cells using either X-gal or a fluorescent methylumbelliferyl B-galactosidase derivative. The promoter hsp60 gene highly expressed the lacz gene in both M. smegmatis and BCG.

10

15

20

5

The FF<u>lux</u> gene was cloned into pMV261 downstream from the hsp60 promoter in plasmid pYUB180 (see Figure 2), which plasmid was shown to express the FF<u>lux</u> gene in <u>M. smegmatis</u>, BCG and <u>M. tuberculosis</u> The expression of the $FF\underline{lux}$ gene was detected by observing luminescence of mycobacterial clones containing the cloned gene in the dark room, and verified use in photographic film. This demonstrated that the luciferase was expressed in the mycobacteria, and that luciferin, the substrate used, was able to penetrate mycobacterial cell walls and yield photons expressed by the mycobacteria.

Detection of Photons In Mycobacterial Cells Expressing FFlux

The expression of FF<u>lux</u> from the plasmid pYUB180 in <u>M. smegmatis</u> provided a model with which to determine a minimal number of individual cells

10 -

15

25

detectable with the luciferase assay. M. smegmatis containing pYUB180 were grown in the presence of kanamycin to ensure that every cell contained the plasmid. The cells were diluted 10-fold serially and the amount of luciferase activity was determined using a luminometer. Figure 3 shows that the amount of luciferase activity from 5×10^7 cells approached luciferase units, though at this 108 activity the luminometer was unable to accurate measurement. However, the activity decreased in a linear manner down to 1200 units for 500 cells. Hence, 5000 cells expressing the FFlux gene can be clearly discerned above the background measurement, which approaches the number of cells that one would expect to observe in clinical samples.

Distinguishing Drug-Resistant Mycobacteria From Drug-Sensitive Mycobacteria Using Luciferase Activity

Since Firefly luciferase activity requires ATP, and ATP is produced only by living cells which are metabolically active, luciferase is a powerful indicator of the metabolic abilities of a bacterial Since anti-tuberculosis drugs are likely to cell. significantly decrease the metabolic activity of a cell, the measurement of luciferase activity should distinguishing οf sensitive means provide а drug-sensitive mycobacteria from drug-resistant mycobacteria.

First, the kinetics of the production of luciferase activity of M. smegmatis containing pyuBl80 following the addition of streptomycin, isoniazid, ethambutol, rifampicin, ciprofloxacin, novobiocin or cyanide, added at levels that inhibit the growth of M. smegmatis in plate assays, was measured.

As shown in Figure 4, Panel A, the levels of luciferase production were 100 to 1000 times less at eight hours after the addition of the drugs compared to the untreated control.

Next, this approach was used to distinguish drug-resistant from drug-sensitive mycobacteria. pYUB180 deposit was transformed streptomycin-resistant or novobiocin-resistant M. smegmatis mutants. Photon production the drug-sensitive parent was compared the streptomycin-resistant or novobiocin-resistant mutants. The drug-resistant mutants continued to produce luciferase activity levels comparable to the 20 untreated patent in the presence of the appropriate antibiotic. In addition, the drug-resistant mutants produced 100 to 1000 times more luciferase activity than the drug-sensitive parent (see Figure 4, Panels B and C). Hence, a luciferase-based assay may be used to determine mycobacterial drug susceptibility.

2 12

Construction of TM4 Reporter Mycobacteriophages and Detection of Photons Following TM4:: lux Infection

The first vectors developed to introduce recombinant DNA into mycobacteria were shuttle phasmid phage vectors. Shuttle phasmids have the ability to replicate in <u>E. coli</u> as cosmids and then replicate in mycobacteria as phages. Shuttle phasmids of TM4 which contained the FF<u>lux</u> and <u>lac</u>Z genes transcribed from hsp60 and Ll promoters, respectively, were constructed (see Figure 5).

A deposit of the shuttle phasmid (reporter which mycobaceriophage) phAE39 mycobacteriophage TM4, cosmid pYUB216, reporter gene FFlux and promoter hsp60, was made with the American January 12, 1992 and Type Culture Collection on catalogued as ATCC #75183. When the TM4:: lux shuttle phasmid phAE39 was mixed with M. smegmatis cells, detected within luciferase activity could be minutes of incubation, and continued to increase slightly over the next 4 hours (see Figure 6). These results show that the TM4:: lux mycobacteriophage is FF<u>lux</u> gene capable of introducing the mycobacterial cells, and that the FFlux gene can be expressed in mycobacteriophage-infected cells. Figure 7 represents a flow chart for cloning different promoters into the TM4:: lux shuttle phasmid phAE39.

A deposit of the shuttle phasmid (reporter

10:

·15

20

mycobacteriophage TM4, cosmid pYUB216, reporter gene lacZ and promoter Ll, was made with the American Type Culture Collection on _______, 1992 and catalogued as ATCC #______. The TM4::lacZ mycobactericphage formed bright blue plaques when plated on media containing X-gal.

Construction of the L5 Reporter Mycobacterophage

Strategies for construction of the recombinant L5 mycobacteriophage may be investigated. The possibility of using the shuttle phasmid approach starting with L5 deletion derivatives, in which the size of the genome has been reduced, may also be explored. Initially, the largest gene 62 deletion available should be used. However, other deletion derivatives in which more of the gene 62-61-60 segment is lost should also be isolated. Another approach would be to attempt to introduce genes by homologous recombination with plasmids. Still another approach would be to transpose lux genes onto L5 using either the mini-Mu in vitro transposition system or a mycobacterial transposon such as IS1096.

Recombining reporter genes from recombinant plasmids onto L5 using a double recombination event

25 may also be performed. This involves first constructing a recombinant plasmid that carries a reporter gene (lacZ may be more suitable) inserted

.....**5**

10

(: :

20

25

gene 62 such that both the upstream into downstream parts of gene 62 are present. Advantages of this approach are that lacZ can be easily detected in agar media, that gene 62 is not an essential gene, and that lacZ is efficiently expressed from a promoter immediately upstream of gene 62. L5 mycobacteriophage lysate may be prepared by growth of the plasmid-containing strain and recombinant mycobacteriophage progeny identified by plating the lysate on wild-type M. smegmatis for plaques on agar containing the indicator X-gal.

This recombination approach may be expanded to introduce other gene or DNA segments of the L5 genome. For example, it should be possible to add luciferase genes from FFlux in an identical manner, provided that packaging limits are not exceeded. addition, inclusion of polylinker containing restriction enzyme sites unique for L5 would open the way for construction of L5 recombinants in vitro. Similar genetic strategies may useđ systematically reduce the size of the L5 genome by deletion of non-essential sequences.

> Transposition offers an alternative method for the construction of reporter mycobacteriophages. A transposition system which is available is the mini-Mu in vitro transposition system. This is a defined biochemical reaction in which a mini-Mu transposon

15

20

carrying the desired gene is transposed onto the phage genome using purified MuA and MuB proteins. Similar transposition experiments have been tried with L5, but few L5 mini-Mu derivatives have been isolated. It is possible that this is due to the relatively large size of the transposon used. It is necessary to first construct a small Mu transposon which contains the reporter gene, a promoter and the two Mu in order for these experiments to be successful.

Development of L5 in vivo and in vitro Packaging Systems

g cosmids and packaging systems provide the efficiency of mycobacteriophage infection with the ability inject segments large οf non-mycobacteriophage DNA. Analogous mycobacterial systems would overcome packaging constraints encountered with recombinant mycobacteriophage genomes and allow the introduction of multiple copies or types reporter genes into mycobacteria, potentially enhancing the sensitivity of the assay. In addition, they would help overcome any problems with host synthesis inhibition.

The development of L5 cosmids and packaging systems is dependent on the finding that the L5 genome contains cohesive termini. The g paradigm suggests that a relatively small region of DNA (approximately 500bp) around the cos site (in the ligated form) is

necessary to promote packaging. The first series of experiments with L5 would therefore be to identify the segment of the genome required for packaging constructing a series of plasmids containing the L5 cos site and surrounding sequences. Cos activity may be determined by preparation of an L5 lysate on plasmid-containing M. smegmatis strains, followed by the identification of antibiotic-resistant transductants in the lysate, by transduction assay assumes that plasmid M. smegmatis. This 10 multimers of a total size of approximately 50kb are present in the cell and will be packaged. Although multimers has not the presence of such demonstrated directly, they are likely to be generated homologous recombination system the 15 by M. smegmatis. If this assay should fail, cosmid vectors which contain both L5 g cos sites may be constructed. Insertion of 40-45kb of DNA (as in the construction of cosmid libraries) followed by g . - . packaging in vitro and infection with E. coli will 20 generate 50kb sized molecules containing L5 cos site. These should be isolated from E. coli and introduced by electroporation into M. smegmatis. Assuming that one of these approaches is successful, it would then 25 be possible to define a small segment of L5 DNA required for packaging.

The construction of in vivo cosmid packaging

15

systems is a particularly attractive idea since it has proven very useful in <u>E. coli</u>. Thermoinducible lysogens of L5 may be suitable for <u>in vivo</u> packaging of L5 cosmids without further modification, since prophage excision may be a temperature-sensitive event. Efficient packaging of extrachromosomal cosmids present in the lysogen may be achieved by simple induction and growth at 42°C.

It is possible that some process other than excision is temperature-sensitive in induction. If so, it will be necessary to further debilitate the prophage in order to prevent DNA packaging of the prophage. There are a variety of ways to accomplish this. For example, the excise gene itself could be deleted (using a recombination strategy similar to that described above) such as to prevent excision. Another approach is to damage the cohesive termini (by exonucleolytic digestion) of an L5 _ thermoinducible derivative and construct a defective lysogen. A combination of approaches may be desirable, since even if prophage excision is a temperature-sensitive process, the destruction of cos might effectively reduce the background of spontaneous mycobacteriophage release.

Construction of <u>in vitro</u> packaging systems will follow similar lines. Extracts may be prepared from thermoinducible strains with non-packagable

- 10

prophages and assessed for their ability to package exogenously added L5 cosmid or mycobacteriophage DNA. Optimization of conditions should follow both empirical a biochemical approaches and the well-established g systems. For example, it may be necessary to supplement the extracts with purified mycobacteriophage products such as the terminase or the tape-measure analogues (genes A/Nu and H of g respectively), neither of which yet have been identified.

Construction of Novel Shuttle Phasmids From Any Mycobacteriophage

Although mycobacteriophages L5 and TM4 can be used in the development of diagnostic luciferase and 15 B-galactosidase shuttle phasmids, there may be other mycobacteriophages, such as the mycobacteriophage DS6A which only infects BCG and M. tuberculosis strains, that might prove to have a more useful host range for clinical isolates. Diagnostic luciferase mycobacteriophages from these other mycobacteriophages 20 may be developed by using the shuttle methodology described herein that has been proven successful for constructing mycobacteriophage vectors from both TM4 and phage L1.

25 Isolate Mycobacteriophage L5 and TM4 Mutants to Infect the Maximum Number of Clinial Isolates

For the diagnostic luciferase mycobacteriophage system to have maximal use in the clinical laboratory,

15

it will be essential that to develop a diagnostic mycobacteriophages that can efficiently infect any clinical isolate and possibly distinguish BCG. M. tuberculosis from M. avium and mycobacteriophages TM4 and L5 appear to have ability to infect a large number of M. tuberculosis isolates. TM4 is very closely related to phage 33D, a mycobacteriophage that has been found not to infect every M. tuberculosis isolate used to define mycobacteriophage typing schemes for M. tuberculosis isolates. However, this mycobacteriophage does not infect BCG. TM4 has been found to be almost identical by DNA hybridization and restriction analysis to 33D, and it shares the host-specificity with 33D in that it infects M. tuberculosis, but fails to infect BCG. mycobacteriophage L5 appears to share the same receptor as mycobacteriophage D29 which receptor has been previously shown to infect a very large number of L5, unlike 33D M. tuberculosis isolates. OI infects all three morphotypes of M. avium including a wide range of serovariants.

If L5 or TM4 are found not to infect certain M. tuberculosis isolates, it may be possible to isolate mutants of these mycobacteriophages which plaque on the particular isolate. The inability to plaque on a particular isolate could result from the lack of a mycobacteriophage receptor or be the result

25

10

of lysogenization of the isolate with a homoimmune phage. Phage mutants with altered host range specificities or mutants which no longer bind a repressor (equivalent to virulent mutant of g) have been isolated in other systems. Variants of TM4 which can efficiently infect BCG have been isolated at frequencies of 10⁷. Previous work has demonstrated that 33D, similarly to TM4, can not adsorb to BCG cells. Host-range variants of TM4 which not only plaque BCG, but also still plaque M. tuberculosis have been isolated. Similar strategies for M. tuberculosis isolates which are uninfected by L5 or TM4 may be used.

Detecting the Presence of M. tuberculosis in Clinical Samples

The combined sensitivities of luciferase and mycobacteriophage infections should permit the detection of previously undetectable levels of M. tuberculosis cells in sputum, blood samples, or cerebral spinal fluid. A number of preliminary studies to optimize the detection of M. tuberculosis cells in a variety of body samples will be performed.

Detecting <u>M. tuberculosis</u> Grown In Primary Human Macrophages and Macrophage Cell Lines

As a model system for optimizing detection of

M. tuberculosis in infected monocytes and macrophages,
primary human monocytes which have been purified by
adherence for 1 hour or primary macrophages which have

· 5

10

cultured for 6 days in microwells will be infected with M. tuberculosis H37Ra at varying multiplicities. The number of cells initially infected will be determined microscopically, and then at various periods of time from 2 hours to 30 days, the cells will by lysed by non-ionic detergent NP40 which has no effect on viability of mycobacteria, concentrated by centrifugation, plated for viable organisms and infected with the luciferase plasmids. Quantitative studies at different moi's and with varying numbers of infected cells will indicate how few bacilli/cell and bacilli/specimen can be detected.

The inability of M. tuberculosis cells isolated from macrophages to be infected with diagnostic shuttle phasmids could result from either the absence of the expression of the mycobacteriophage-receptor or the masking of the receptor with a membrane from a The level of expression phagosome of the macrophage. of phage receptors may be regulated by the environment in which the host cell is grown. For example, the g E. coli is induced by maltose repressor by glucose. Studies to identify repressed mycobacteriophage have receptors for L5 initiated. Similar studies for mycobacteriophage TM4 will also be performed. By identifying the genes encoding the receptor, it is possible to assay gene the mycobacteriophage receptor repression οf

25

25

M. tuberculosis cells when grown in macrophages by hybridization for the mRNA synthesis. If the receptor is not expressed in macrophages, it may be necessary to use a mycobacteriophage which recognizes a receptor that is constitutively expressed.

If the receptor is masked by a membrane of the macrophage, the cells isolated from macrophages may be treated with a variety of different detergents to find a treatment that would allow infection of M. tuberculosis cells with the mycobacteriophages. Again, it may be necessary to cultivate detergent-treated macrophages in broth for a generations to gain expression of the receptors. assays to determine the infectability of macrophages from mycobacteria include not only the luciferase assay for the TM4:: lux mycobacteriophages, but also assays in which infectious centers removed are and mycobacteriophages mycobacteriophage-producing cells are scored mixed plating on a lawn of M. smegmatis. This assay would be useful since infectability can be scored even if there are insufficient M. tuberculosis cells to form a bacterial lawn. It is important to re-evaluate specificities all οf the the host range in mycobacteriophages this mycobacteriophages can simply be removed through the use of specific anti-mycobacteriophage antibodies.

Detecting M. tuberculosis in Sputum Samples

Sputum from a patient infected M. tuberculosis contains a ... mixture of mucoploysaccharide, free M. tuberculosis cells, macrophages containing M. tuberculosis cells and a variety of cellular debris. Sputum samples from patients thought to have pulmonary tuberculosis may be used for a study in which various numbers of M. tuberculosis cells are added to sputum samples found to have no or few organisms by 10. staining. A variety of methods can be used to treat sputum samples so as to liquify the mucous and decontaminate the specimen under conditions in which bacteria other than mycobacteria are killed. Because of the specificity of the phasmids, 15 decontamination may not be as important as preserving the mycobacteriophage receptors. Nonetheless, sputum samples may be treated initially with 2% w/v NaOH for 30 minutes at 37°C or with 0.5% N-acetyl cysteine + 1% NaOH. Alternatively, the sample may be treated with a variety of hydrolytic enzymes, such as collagenase, to help dissolve the sputum sample. mycobacteriophage receptors are carbohydrates possibly sensitive to these conditions, other conditions may be utilized or the cells will be cultured 3-16 hours to allow recovery of infectivity before mycobacteriophage infection.

20

25

Detecting Mycobacteria In Blood Samples

Tuberculosis has been known to have bacteremia. If the sensitivity necessary to detect 100 to 200 M. tuberculosis cells in a ml of sample can be obtained, levels of bacteremia in tuberculosis patients which were not previously observable may be observed. White cells should be purified over Ficoil-hypaque and lysed with 2% NP40, 1% SDS or freeze-thawing in the presence of DNAse to liberate intracellular mycobacteria. The pellet should then be infected with the diagnostic luciferase mycobacteriophage, or if only few organisms present they can be concentrated by filtration onto filters, and filter areas cut out and infected.

Assuring Specificity On a Variety of Clinical Isolates and Species; Assessment of False Positives and Negatives

The luciferase assay may be optimized such that positive correlations of M. tuberculosis infections as indicated in the clinical lab may be obtained. recombinant mycobacteriophages may bе tested ascertain the range of specificity that they have for other mycobacteria, and for the closely related genera Norcardia, Corynebacterium, and Actinomycetes strains. These strains may be obtained from the A number of blinded tests including negative controls, M. tuberculosis-infected patients, samples

from patients infected with <u>M. avium</u>, and samples infected with other non-mycobacterial pathogens may be performed to ascertain the range of specificity.

assess the to rapidly ability The M. tuberculosis isolates to susceptibilities of isoniazid, ethambutol, rifampicin, pyrazinamide other antibiotics will have a major impact on the patients. After treatment of tuberculosis isolation of <u>M. tuberculosis</u> cells from a sputum sample, which may take several weeks, the assessment of drug-susceptibilities may take an additional 2 to 9 Diagnostic reporter mycobacteriophages may allow for evaluations of drug-susceptibilities at the time a sputum sample is collected. Alternatively, this approach would shorten the time necessary to purified drug-susceptibilities of assess clinical M. tuberculosis colonies grown from up samples.

Luciferase Assays for M. tuberculosis Cells in the Presence of Drugs

20

25

The results of the experiments suggest that by using luciferase as an indicator for the metabolic ability of the cell, it may be possible to define conditions which will enable us to distinguish drug-resistant mycobacteria from drug-sensitive mycobacteria. To test this hypothesis, isolated

mutants of <u>M. tuberculosis</u> H37Ra which are resistant to isoniazid, rifampicin, ethambutol, or pyrazinamide would be used to generate a set of cogenic mutants. These independent mutants and the parent strains would be transformed with pyubl80. Luciferase activity will be assessed in the presence and absence of drugs in order to determine the optimal conditions for distinguishing between drug-resistant and drug-sensitive cells. It is quite possible that the window of time to observe differences for different drugs could vary and require different incubation times for each drug.

The choice of the promoter for expressing luciferase may provide a needed parameter to more readily assess drug action. For example, in the case of <u>E. coli</u>, gyrase promoters are greatly stimulated in the presence of gyrase inhibitors.

Clinical isolates of <u>M. tuberculosis</u> may be transformed with PYUB180 and tested for luciferase 20 activity in the presence and absence of drugs. The luciferase assays with mycobacteriophage infections with lux mycobacteriophages on <u>in vitro-grown M. tuberculosis</u> cells will first be optimized, and then extended to <u>M. tuberculosis</u> cells grown in macrophages or isolated from sputum samples.

Critical Assessment of Drug-Susceptibility Testing

15

. 20

As for the detection of M. tuberculosis from samples, the luciferase assay clinical optimized so that the drug-susceptibility patterns for any clinical isolate may be obtained. possible to add diagnostic mycobacteriophages to a single clinical specimen, aliquot the mixture into various tubes and add antibiotic drugs. Thus every experiment would have an internal control and each drug-treated sample could be compared to an untreated control. The critical parameter to drug-resistance or sensitivity lies in the comparison.

Although the invention herein described with reference to particular embodiments, it is to be understood that these embodiments are merely illustrative of various aspects of the invention. it understood that is to be illustrative the modifications may be made in embodiments and other arrangements may be devised without departing from the spirit and scope of the invention.

20

WHAT IS CLAIMED IS:

- species-specific reporter mycobacteriophages which comprises introducing reporter genes and transcriptional promoters into the genomes of mycobacterial species-specific mycobacteriophages wherein upon incubation with the mycobacteria for which said reporter mycobacteriophage is specific, the reporter genes of said reporter mycobacteriophage will express a gene product which is detectable.
- 2. The method according to Claim 1 wherein the reporter genes and transcriptional promoters are introduced into the mycobacteriophages by shuttle phasmid technology.
- 3. The method according to Claim 1 wherein the reporter genes and transcriptional promoters are introduced into the mycobacteriophages by homologous recominbation or PCR.
 - 4. The method according to Claim 1 wherein the reporter genes and transcriptional promoters are introduced into the mycobacteriophages by transposon technology.
 - 5. The method according to Claim 1 wherein the reporter genes and transcriptional promoters are

10

introduced into the mycobacteriophages by debilitated phages packaged into page heads and tails.

- 6. The method according to Claim 1 wherein the reporter genes and transcriptional promoters are introduced into the mycobacteriophages by plasmids packaged into phage heads and tails.
- 7. The method according to Claim 1 wherein the reporter genes and transcriptional promoters are introduced into the mycobacteriophages by recombinant DNA techniques.
- 8. The method according to Claim 1 wherein the mycobacteria is M. tuberculosis.
- 9. The method according to Claim 1 wherein the mycobacterial species-specific mycobacteriophage 15 is L5, TM4 or DS6A.
 - 10. The method according to Claim 1 wherein the reporter genes are luciferase genes or the β -galactosidase gene.
 - 11. The method according to Claim 10 wherein

 the luciferase genes are selected from the group consisting of Firefly <u>lux</u> gene, <u>Vibrio fischeri lux</u> genes, <u>Xenorhabdus luminescens lux</u> genes and <u>lac</u>Z genes.
- 12. The method according to Claim 1 wherein the transcriptional promoter is hsp60 or the L5 gene 62 promoter.

20.

- 13. The method according to Claim 1 wherein the gene product is photons.
- 14. The method according to Claim 1 wherein the gene product is made detectable by contacting said gene product with a substrate.
 - 15. The method according to Claim 14 wherein the substrate is luciferin or decanal.
- 16. The mycobacterial species-specific reporter mycobacteriophage produced by the method of 10 Claim 1.
 - mycobacterial species-specific reporter mycobacteriophage comprising a mycobacterial species-specific mycobacteriophage which contains in its genome reporter genes and a transcriptional promoter, wherein the reporter genes express a gene product upon incubation with the mycobacteria for which the reporter mycobacteriophage is specific.
 - 18. The mycobacterial species-specific reporter mycobacteriophage according to Claim 17 wherein the mycobacteria is M. tuberculosis.
 - 19. The mycobacterial species-specific reporter mycobacteriophage according to Claim 17 wherein the mycobacterial species-specific mycobacteriophage is L5, TM4 or DS6A.
- 25 20. The mycobacterial species-specific reporter mycobacteriophage according to Claim 17

wherein the reporter genes are luciferase genes or the ß-galactosidase gene.

- 21. The mycobacterial species-specific reporter mycobacteriophage according to Claim 20 wherein the luciferase genes are selected from the group consisting of Firefly lux gene, Vibrio fischeri lux genes, Xenorhabdus luminescens lux genes and lacz genes.
- 22. The mycobacterial species-specific

 10 reporter mycobacteriophage according to Claim 17

 wherein the transcriptional promoter is hsp60 or the

 L5 gene 62 promoter.
 - 23. The mycobacterial species-specific reporter mycobacteriophage according to Claim 17 wherein the gene product is photons.
 - 24. The mycobacterial species-specific reporter mycobacteriophage according to Claim 17 wherein the gene product is made detectable by contacting said gene product with a substrate.
 - 25. The mycobacterial species-specific reporter mycobacteriophage according to Claim 24 wherein the substrate is luciferin or decanal.
- 26. A method of diagnosing a mycobacterial disease which comprises incubating a sample which may contain myco- bacteria with mycobacterial species-specific mycobacteriophages which contain

15

20

80 30 60

reporter genes and transcriptional promoters in their genomes, wherein the reporter genes produce a gene product upon incubation with the mycobacteria for which the mycobacteriophage is specific, and wherein the gene product is detectable.

- 27. The method according to Claim 26 wherein the mycobacterial disease is tuberculosis.
- 28. The method according to Claim 26 wherein the mycobacteria is <u>M. tuberculosis</u>.
- 10 29. The method according to Claim 26 wherein the mycobacterial species-specific mycobacteriophage is L5, TM4 or DS6A.
 - 30. The method according to Claim 26 wherein the reporter genes are luciferase genes or the ß-galactosidase gene.
 - 31. The method according to Claim 30 wherein the luciferase genes are selected from the group consisting of Firefly <u>lux</u> gene, <u>Vibrio fischeri lux</u> genes, <u>Xenorhabdus luminescens lux</u> genes and <u>lac</u>Z genes.
 - 32. The method according to Claim 26 wherein the transcriptional promoter is hsp60 or the L5 gene 62 promoter.
- 33. The method according to Claim 26 wherein25 the gene product is photons.
 - 34. The method according to Claim 26 wherein

(3.1.)

10

20

the gene product is made detectable by contacting said gene product with a substrate.

- 35. The method according to Claim 34 wherein the substrate is luciferin or decanal.
- 36. The method according to Claim 26 wherein the sample is blood or sputum.
 - 37. A method of assessing drug resistance of a mycobacterial strain which comprises:
 - (a) incubating a sample which contains a myco- bacterial strain with mycobacterial species-specific mycobacteriophages which contain in their genomes transcriptional promoters and reporter genes which produce gene products;
- (b) adding an anti-mycobacterial drug to the incubation; and
 - (c) detecting whether the gene product is present in the sample, such presence indicating drug resistance of the mycobacterial strain.
 - 38. The method according to Claim 37 wherein the mycobacterial strain is a strain of M. tuberculosis.
 - 39. The method according to Claim 37 wherein 25 the mycobacterial species-specific mycobacteriophage is L5, or TM4 or DS6A.

20

- 40. The method according to Claim 37 wherein the reporter genes are luciferase genes or the β -galactosidase.
- 41. The method according to Claim 40 wherein the luciferase genes are selected from the group consisting of Firefly <u>lux</u>, gene, <u>Vibrio fischeri lux</u> genes, <u>Xenorhabdus luminescens lux</u> genes and <u>lac</u>Z genes.
 - 42. The method according to Claim 37 wherein to the gene product is photons.
 - 43. The method according to Claim 37 wherein the transcriptional promoter is hsp60 or the L5 gene 62 promoter.
 - 44. The method according to Claim 37 wherein the anti-mycobacterial drug is selected from the group consisting of streptomycin, isoniazid, ethambutol, rifampicin, ciproflo-xacin, novobiocin and cyanide.
 - 45. The method according to Claim 37 wherein the gene product is made detectable by contacting said gene product with a substrate.
 - 46. The method according to Claim 45 wherein the substrate is luciferin or decanal.
 - 47. The method according to Claim 37 wherein the sample is blood or sputum.
